Agenda

- Web Services
- RPCs
- SOAP 1.2
- WSDL 1.1
- Axis 1.4
## Web Services

### History

- **SOAP in 1998**
- **XML-RPC**
  - Dave Winer of UserLand Software, 1998
- **SOAP since 1999**
  - Based on XML-RPC
  - Version 0.9 released in late 1999 by Microsoft, DevelopMentor, and Dave Winer
  - Version 1.0 followed soon thereafter
  - Version 1.1 submitted as a W3C note May 2000 by DevelopMentor, IBM, Lotus, Microsoft, and UserLand Software
  - IBM and Microsoft release toolkits. IBM donates toolkit to Apache
  - Many vendors implement SOAP
Web Services

Architecture

- The web services architecture is an evolution of existing technologies
  - The Internet enables hosts to communicate and information to be published and retrieved
  - Distributed computing platforms allow programmatic components to communicate
  - XML closes the barriers between platforms and technologies
RPCs

Remote Procedure Calls

- Two pieces of code (client and server) talk over the network, generally using TCP/IP sockets
- The client need not be aware that it is not using a local class
  - Client-side *stub* implements the service interface and takes care of serializing/marshalling the arguments for transmission over the network. The stub makes the network call and hands the response back to the caller
- The remote object (server) need not be aware that it is not called by a local class
  - Server-side *skeleton* handles deserializing/unmarshalling the arguments and calling the local class, sending back the result to the remote client
SOAP 1.2

What

- SOAP (Simple Object Access Protocol) is used to serialize a remote procedure call (RPC) across the network
- Has its roots in distributed computing technologies
  - DCOM
  - CORBA
  - Java RMI
SOAP 1.2

What

- SOAP is a lightweight mechanism for exchanging structured and typed information between peers in a decentralized, distributed environment using XML.
- SOAP is an XML-based protocol that consists of three parts:
  - An envelope that defines a framework for describing what is in a message and how to process it.
  - A set of encoding rules for expressing instances of application-defined datatypes (i.e., how to serialize data structures).
  - A convention for representing remote procedure calls and responses.
SOAP 1.2

HTTP Request

POST /warehouse/services/Purchasing HTTP/1.0
Content-Type: text/xml; charset=utf-8
Accept: application/soap+xml, application/dime, multipart/related, text/*
User-Agent: Axis/1.3
Host: 127.0.0.1
Cache-Control: no-cache
Pragma: no-cache
SOAPAction: ""
Content-Length: 412

<?xml version="1.0" encoding="UTF-8"?>
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
                 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
                 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <soapenv:Body>
    <processPO
      soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
      <arg0 xsi:type="xsd:string">&lt;PO/&gt;</arg0>
    </processPO>
  </soapenv:Body>
</soapenv:Envelope>
SOAP 1.2

HTTP Response

HTTP/1.1 200 OK
Server: Apache-Coyote/1.1
Content-Type: text/xml;charset=utf-8
Date: Wed, 13 Apr 2005 14:09:02 GMT
Connection: close

<?xml version="1.0" encoding="UTF-8"?>
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
                 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
                 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <soapenv:Body>
    <processPOResponse
      soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
      <processPOReturn xsi:type="xsd:string">&lt;PO-ACK/&gt;</processPOReturn>
    </processPOResponse>
  </soapenv:Body>
</soapenv:Envelope>
SOAP 1.2

Envelope

- **Envelope** is the top-level element. It defines the various namespaces used in the message
  - **Header** is an optional element used for carrying extra information about authentication, transactions, *etc.*
  - **Body** is the element containing the payload of the message
The SOAP specification describes how to serialize application-specific data-types into and out of an XML representation:

- XML Schema primitive types (int, byte, short, boolean, string, float, double, date, time, and URL) are sent as-is.
- More complicated objects (e.g., Java classes) must have a matching schema and a mechanism for serializing into/out of schema.
SOAP 1.2

SOAP Router

- A SOAP router
  - Listens on the appropriate protocol
  - Receives SOAP request
  - Has a binding between service's URN and implementing class
  - Calls appropriate class to handle request
  - Returns response to sender
- Apache provides a SOAP router called “Axis” that is an HTTP servlet that can be deployed in any webserver or servlet container
WSDL 1.1

What

- WSDL (Web Services Description Language) describes
  - what a web service can do
  - where it resides
  - how to invoke it
- WSDL is usually used with SOAP as a transport protocol, although it can work with other protocols as well
WSDL 1.1 definitions

<definitions name="CurrencyExchangeService"
    targetNamespace="http://www.xmethods.net/sd/CurrencyExchangeService.wsdl"
    xmlns:tns="http://www.xmethods.net/sd/CurrencyExchangeService.wsdl"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap"
    xmlns="http://schemas.xmlsoap.org/wsdl/">

    <message name="getRateRequest">...</message>
    <message name="getRateResponse">...</message>

    <portType name="CurrencyExchangePortType">
        ...
    </portType>

    <binding name="CurrencyExchangeBinding" type="CurrencyExchangePortType">
        ...
    </binding>

    <service name="CurrencyExchangeService">
        ...
    </service>

</definitions>

WSDL 1.1

message

<message name="getRateRequest">
    <part name="country1" type="xsd:string"/>
    <part name="country2" type="xsd:string"/>
</message>

<message name="getRateResponse">
    <part name="return" type="xsd:float"/>
</message>

A message is a single transmission of information going between the two parties; it has multiple parts that have either simple types (primitives) or more complicated types (defined in a schema).

WSDL 1.1

portType

<portType name="CurrencyExchangePortType">
  <operation name="getRate">
    <input message="getRateRequest"
      name="tns:getRate"/>
    <output message="getRateResponse"
      name="tns:getRateResponse"/>
  </operation>
</portType>

A portType corresponds to a set of one or more operations, where each operation defines a specific input/output sequence; corresponds to the programmatic notion of an interface.
WSDL 1.1

binding

(binding name="CurrencyExchangeBinding" type="CurrencyExchangePortType">
  <soap:binding style="rpc"
    transport="http://schemas.xmlsoap.org/soap/http"/>
  <operation name="getRate">
    <soap:operation soapAction=""/>
    <input>
      <soap:body use="encoded"
        namespace="urn:xmethods-CurrencyExchange"
        encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"/>
    </input>
    <output>
      <soap:body use="encoded"
        namespace="urn:xmethods-CurrencyExchange"
        encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"/>
    </output>
  </operation>
</binding>

A binding describes how a portType is implemented over a particular protocol; the soap message body is created using the type encoding specified by the soap specification. In this case, the protocol is RPC-style SOAP.
WSDL 1.1

A service is a collection of related endpoints, described by documentation; a port describes the availability of a particular binding at an endpoint.
When a WSDL document declares operations that take more complicated types, XML Schema type definitions are included beneath the WSDL document's definitions element.

```xml
<xsd:schema targetNamespace="urn:AddressFetcher2" xmlns:xsd="http://www.w3.org/1999/XMLSchema">
  <xsd:simpleType name="stateType">
    <xsd:restriction base="xsd:string">
      <xsd:enumeration value="TX"/>
      <xsd:enumeration value="IN"/>
      <xsd:enumeration value="OH"/>
    </xsd:restriction>
  </xsd:simpleType>
</xsd:schema>
```

WSDL 1.1

Document Style

- Web service designers/users often think of the XML representation merely as the "wire format"
- They want RPC-style invocation, with binding to programmatic objects on both sides via serialization
- But sometimes, we want to just use WSDL/SOAP to send an XML document, without the RPC semantics
- To do this, we specify `<soap:binding style="document">` in the WSDL file
WSDL 1.1

Tools

- Toolkits help automate
  - Generating client code from a WSDL file for invoking the web service it describes
  - Generating a WSDL file from an object (Java, COM, Visual Basic class)
